## Continuous Domain Search/Optimization

## The problem

- Minimize a **fitness function** (*objective function*, *loss function*) in continuous domain

$$f : \mathcal{S} \subseteq \mathbb{R}^n \rightarrow \mathbb{R},$$

- in the **Black Box scenario** (direct search)

## Hypotheses

- domain specific knowledge only used within the black box
- gradients are not available

## Continuous Domain Search/Optimization

# The problem

- Minimize a **fitness function** (*objective function*, *loss function*) in continuous domain

$$f : \mathcal{S} \subseteq \mathbb{R}^n \rightarrow \mathbb{R},$$

- in the **Black Box scenario** (direct search)

## Typical Examples

- shape optimization (e.g. using CFD)      curve fitting, airfoils
- model calibration      biological, physical
- parameter identification      controller, plants, images

well, almost – see later

## Goal

- Empirical comparison
  - on some artificial testbed
  - illustrating typical difficulties of continuous optimization
  - between
    - some bio-inspired algorithms
    - and some (one!) deterministic optimization method(s)
  - in the back-box scenario
- without specific intensive parameter tuning

# Bio-inspired Optimization Algorithms

# Darwinian Artificial Evolution

Repeat (Parent selection – Variation – Survival selection)

## Preselection: Results of CEC'05 Challenge

- Particle Swarm Optimization Eberhart & Kennedy, 95
  - Perturb particle velocity  $\rightarrow$  *best* and *local best*
  - Update *best* and *local best*
- Differential Evolution Rainer and Storn, 95
  - Add difference vector(s)
  - Uniform crossover with proba.  $1 - CR$
  - Keep best of parent and offspring
- Covariance Matrix Adaptation-ES Hansen & Ostermeier, 96
  - Gaussian mutation + Update mutation parameters
  - Keep  $\frac{\lambda}{2}$  best of  $\lambda$  offspring

- Compute  $x_{t+1}$  and update  $\hat{H}_t \rightarrow \hat{H}_{t+1}$
- Converges if **quadratic approximation** of  $\mathcal{F}$  holds  
around the optimum
- Reliable and robust  
on quadratic functions!

- 1 Continuous optimization and stochastic search
- 2 Problem difficulties
  - Ruggedness
  - Ill-Conditioning
  - Non-separability
- 3 Implementations and parameter settings
- 4 Experiments and results
- 5 Conclusion

## What makes a problem hard?

- Non-convexity
  - invalidates most of deterministic theory
- Ruggedness
  - non-smooth, discontinuous, noisy
- Multimodality
  - presence of local optima
- Dimensionality
  - line search is 'trivial'
  - The magnificence of high dimensionality
- Ill-conditioning
- Non-separability

- has no population :-)
- but starting point is crucial on multimodal functions
- Replace population by multiple restarts
  - from uniformly distributed points
  - or from the perturbed final point of previous trial

the Hessian is anyway reset to  $I_n$

### III-Conditionning

- The **Condition Number (CN)** of a positive-definite matrix  $\mathbf{H}$  is the ratio of its largest and smallest eigenvalues
- If  $f$  is **quadratic**,  $f(\mathbf{x}) = \mathbf{x}^T \mathbf{H} \mathbf{x}$ , the CN of  $f$  is that of its Hessian  $\mathbf{H}$
- More generally, the CN of  $f$  is that of its Hessian wherever it is defined.

Graphically, ill-conditioned means “squeezed” lines of equal function value

Increased  
→  
condition  
number

**Issue:** The gradient does not point toward the minimum ...

## A priori discussion

## Bio-inspired algorithms

- PSO and DE: population can point toward the minimum
- CMA-ES: covariance matrix can take longer to learn

BFGS

- Numerical gradient can raise numerical problems
- Hessian matrix can take longer to learn

## Rotational invariance

## Bio-inspired algorithms

- PSO: is **not** rotational invariant see next slide
- DE: **Crossover** is not rotational invariant  
Rotational invariance iff  $CR = 1$
- CMA-ES: is rotational invariant

**BFGS**

- Numerical gradient can raise numerical problems  
Added to ill-conditioning effects

$$V_i^j(t+1) = V_i^j(t) + \underbrace{c_1 \mathcal{U}_i^j(0, 1)(p_i^j - x_i^j(t))}_{\text{approach the "previous" best}} + \underbrace{c_2 \tilde{\mathcal{U}}_i^j(0, 1)(g_i^j - x_i^j(t))}_{\text{approach the "global" best}}$$

## PSO and rotational invariance

$$V_i^j(t+1) = V_i^j(t) + \underbrace{c_1 \mathcal{U}_i^j(0, 1)(p_i^j - x_i^j(t))}_{\text{approach the "previous" best}} + \underbrace{c_2 \tilde{\mathcal{U}}_i^j(0, 1)(g_i^j - x_i^j(t))}_{\text{approach the "global" best}}$$

## PSO and rotational invariance

$$V_i^j(t+1) = V_i^j(t) + \underbrace{c_1 \mathcal{U}_i^j(0, 1)(p_i^j - x_i^j(t))}_{\text{approach the "previous" best}} + \underbrace{c_2 \tilde{\mathcal{U}}_i^j(0, 1)(g_i^j - x_i^j(t))}_{\text{approach the "global" best}}$$

## PSO and rotational invariance

$$V_i^j(t+1) = V_i^j(t) + \underbrace{c_1 \mathcal{U}_i^j(0, 1)(p_i^j - x_i^j(t))}_{\text{approach the "previous" best}} + \underbrace{c_2 \tilde{\mathcal{U}}_i^j(0, 1)(g_i^j - x_i^j(t))}_{\text{approach the "global" best}}$$

- 1 Continuous optimization and stochastic search
- 2 Problem difficulties
- 3 **Implementations and parameter settings**
  - Algorithm implementations
  - Tuning DE
- 4 Experiments and results
- 5 Conclusion

- DE: Matlab code from

<http://www.icsi.berkeley.edu/~storn/code.html>

## Not really giving default parameters

- **PSO**: Std PSO 2006, C code from

<http://www.particleswarm.info/Standard> PSO 2006.c

Remark: C code  $\neq$  Matlab code here

- **CMA-ES**: Matlab code from

<http://www.bionik.tu-berlin.de/user/niko/>

- **BFGS**: Matlab built-in implementation using numerical gradient

widely blindly used

- + multiple restarts

local or global

## The problem with DE

## Control parameters

- $NP$ ,  $F$ ,  $CR$ , Stopping Criterion ...
- and strategy to generate difference vector
  - Perturb random or best
  - Number of difference vectors
  - Slightly mutate perturbation
  - All of the above :-)

1 or 2

from public Matlab code

- 1 DE/rand/1
- 2 DE/local-to-best/1
- 3 DE/best/1 with jitter
- 4 DE/rand/1 with per-vector-dither
- 5 DE/rand/1 with global-dither \*
- 6 either-or-algorithm

## the basic algorithm

$$F = rand(F, 1)$$

## Tuning DE

## DE tuning

## Experimental conditions

- Rotated ellipsoid, cond. number =  $10^4$
- Dimension = 10
- Stop when  $f_{elli} < 10^{-6}$

## Design of Experiments

- 6 variants
- $F = \{0.3, 0.5, 0.7, 0.9\}$
- $CR = \{0.3, 0.5, 0.7, 0.9\}$
- $NP = \{3, 5, 10\} \times dim$
- 3 runs per setting :-)

864 runs

Poor DOE, yet totally unrealistic for RWA

## DE Experimental Setting and Discussion

Couldn't decide among 2 variants:

## DE2

- Strategy 2
- $F = 0.8$
- $CR = 1.0$
- $NP = 10 \times dim$

# DE5

- Strategy 5
- $F = 0.4$
- $CR = 1.0$
- $NP = 10 \times dim$

## Discussion

- DE2 very close to 'recommended' parameters
- Except  $CR = 0.9$ , but
- Rotational invariance iff  $CR = 1$  ≡ no crossover

- 1 Continuous optimization and stochastic search
- 2 Problem difficulties
- 3 Implementations and parameter settings
- 4 Experiments and results**
  - Experimental conditions
  - Outputs and Performance measures
  - Results
- 5 Conclusion

unimodal, but non-convex

- Find the best possible fitness value
- At minimal cost Number of function evaluations

- Must take into account both precision and cost
- Usual averages and standard deviations of fitness values irrelevant to assess precision
- **Issue:** need to impose for obvious practical reasons
  - precision threshold on fitness
  - maximum number of iterations

### Average required effort for success

$$SP1 = \frac{\text{avg \# evaluations}}{\text{proportion successful runs}}$$

- Effort to reach a given precision on the fitness (**success**)
- Same number of total fitness evaluations to allow comparisons
- Estimated after a fixed number of **runs**  
High (unknown) variance in the case of few successes
- Could also be estimated after a fixed number of **successes**  
Would allow to control the variance

## A single value, insufficient alone anyway

Rosenbrock function, dim 40, cond. 1000

# Dynamic Behaviors

Median, best, worse, 25-, 75-percentiles

Rosenbrock : 21 trials, dimension 20, tol 1.000E-09, alpha 1000, default size, eval max 10000000

Rosenbrock : 21 trials, dimension 20, tol 1.000E-09, alpha 1000, default size, eval max 10000000

All runs of 2 settings

Comparing DE2 and DE5 on Rosenbrock(1000), dim=20

## Results

## Ellipsoid

- $$f_{\text{elli}}(x) = \sum_{i=1}^n 10^{\alpha \frac{i-1}{n-1}} x_i^2 = x^T H_{\text{elli}} x$$

$$H_{\text{elli}} = \begin{pmatrix} 1 & 0 & \cdots \\ & \ddots & \\ \cdots & 0 & 10^\alpha \end{pmatrix}$$

convex, separable

- $$f_{\text{elli}}^{\text{rot}}(x) = f_{\text{elli}}(\mathbf{R}x) = x^T H_{\text{elli}}^{\text{rot}} x$$

$\mathbf{R}$  random rotation

$$H_{\text{elli}}^{\text{rot}} = \mathbf{R}^T H_{\text{elli}} \mathbf{R}$$

convex, non-separable

- $$\text{cond}(H_{\text{elli}}) = \text{cond}(H_{\text{elli}}^{\text{rot}}) = 10^\alpha$$

$$\alpha = 1, \dots, 10$$

$\alpha = 6 \equiv$  axis ratio of  $10^3$ , typical for real-world problem

## Results

## Separable Ellipsoid function

**PSO**, **DE2**, **DE5**, **CMA-ES**, and **BFGS** - Dimension 10

## Results

## Separable Ellipsoid function

**PSO, DE2, DE5, CMA-ES, and BFGS** - Dimension 40Ellipsoid dimension 40, 21 trials, tolerance  $1e-09$ , eval max  $1e+07$ 

## Ellipsoid: Discussion

### Bio-inspired algorithms

- Separable case: PSO and DE insensitive to conditioning
- ... but PSO rapidly fails to solve the rotated version
- ... while CMA-ES and DE ( $CR = 1$ ) are rotation invariant
- DE scales poorly with dimension  
 $d^{2.5}$  compared to  $d^{1.5}$  for PSO and CMA-ES and BFGS

### ... vs BFGS

- BFGS fails to solve ill-conditioned cases  
Matlab message: *Roundoff error is stalling convergence*  
*Line search couldn't find an acceptable point in the current search direction*
- CMA-ES only 7 times slower  
on quadratic functions!

## Results

## Rosenbrock function (Banana)

$$f_{\text{rosen}}(x) = \sum_{i=1}^{n-1} [(1 - x_i)^2 + 10^\alpha (x_{i+1} - x_i^2)^2]$$

- Non-separable, but ...  
also ran rotated version
- $\alpha = 2$ , classical Rosenbrock function  
 $\alpha = 1, \dots, 10^8$
- Multi-modal for dimension  $> 3$

## Results

## Rastrigin: Discussion

### Bio-inspired algorithms

- Increasing population size improves the results  
Optimal size is algorithm-dependent
- CMA-ES and PSO solve separable case  
PSO about 100 times slower
- Only CMA-ES solves the rotated Rastrigin **reliably**  
requires popSize  $\geq 300$

### ... vs BFGS

- Gets stuck in local optima
- Whatever the restart strategies  
No numerical premature convergence

## Away from “quadraticity”

### Non-linear scaling invariance

- Comparison-based algorithms are insensitive to monotonous transformations    True for DE, PSO and all ESs
- BFGS is not    and convergence results do depend on convexity

### Other test functions

- Simple transformation of ellipsoid

$$f_{\text{SSE}}(x) = \sqrt{\sqrt{f_{\text{elli}}(x)}}$$

- The DiffPow function

and  $\sqrt{\sqrt{\text{DiffPow}}}$

$$f_{\text{DiffPow}}(x) = \sum (|x_i|^{2+(10*i)})$$

## Results

## DiffPow – SP1 vs Fitness Values

PSO, DE2, DE5, CMA-ES, and BFGS - Dimension 10

## Sqrt and DiffPow: Discussion

### Bio-inspired algorithms

- Invariant as expected!
- PSO performs best DiffPow is separable

### ... vs BFGS

- Worse on  $\sqrt{\sqrt{\text{Ellipsoid}}}$  than on Ellipsoid
- Better on  $\sqrt{\sqrt{\text{DiffPow}}}$  than on DiffPow  
'closer' to quadraticity?
- Premature numerical convergence for high CN ...  
fixed by the "local restart" strategy

- 1 Continuous optimization and stochastic search
- 2 Problem difficulties
- 3 Implementations and parameter settings
- 4 Experiments and results**
  - Experimental conditions
  - Outputs and Performance measures
  - Results
- 5 Conclusion

\_\_\_\_\_

- The algorithms
    - Other deterministic methods
    - PCX crossover operator
  - The testbed
    - Noisy functions
    - Constrained functions
  - The statistics
    - Confidence bounds for SP1 and other precision/cost measures
  - Real-world functions
    - Which ones ???
    - Do complete experiments
- e.g. Scilab procedures  
Specific Evolution Engine

- Optimal choice for quasi-quadratic functions
- but can suffer from numerical premature convergence for high condition number
- Even with restart procedures, fails on multimodal problem

dim 10 only here
